

Vyom Energy — Server Access, Start/Stop/Restart & Update Guide

1. Updating the Vyom Energy Web Version

When a new version of the Vyom Energy web application needs to be deployed to the server, follow these steps in order.

Step 1 — Upload the updated code to GitHub

Push/commit the latest changes from your local project to the appropriate GitHub repository.

Make sure the changes are successfully pushed before proceeding.

Step 2 — SSH into the Vyom Energy server

Log in to the **Vyom Energy AWS Lightsail server** using SSH.

You should be able to access the server using your GitHub/server credentials as configured for the project.

Step 3 — Navigate to the repository

Once connected to the server, move into the directory containing the Vyom Energy project.

```
cd <project-directory>
```

Step 4 — Get the latest code

If the repository is already present on the server:

```
git pull
```

If the repository has not been cloned yet:

```
git clone <github-repository-url>
```

Normally, for an existing deployment, **git pull** is what you want.

Step 5 — Stop the currently running server

Before rebuilding, stop the existing Docker containers:

```
sudo docker compose down
```

This shuts down the currently running application containers.

Step 6 — Rebuild and start the server

Start the application again while rebuilding the Docker image/bundle with the latest code:

```
sudo docker compose up --build
```

The `--build` option is important because it ensures the updated code is included in the new build.

Vyom Energy Update Flow

The complete process is:

Local changes → **GitHub** → **SSH into Lightsail** → **Project directory** → `git pull` → `docker compose down` → `docker compose up --build`

2. Updating ERPNext

The ERPNext deployment follows essentially the same process.

Update Flow

1. Make the required changes to the ERPNext-related project.
2. Push the updated code to GitHub.
3. SSH into the server.
4. Navigate to the ERPNext project/repository.
5. Pull the latest changes:

```
git pull
```

6. Stop the running containers:

```
sudo docker compose down
```

7. Start/rebuild the containers:

```
sudo docker compose up --build
```

ERPNext Update Flow

Update GitHub repository → SSH into server → **git pull** → **docker compose down** → **docker compose up --build**

 **Important:** Make sure you are inside the correct project directory before running Docker commands. Running **docker compose down** or **docker compose up** from the wrong directory can affect the wrong Compose project.

3. Starting ERPNext Locally

For local ERPNext development, the project is run through the development Docker environment.

Step 1 — Open the project directory

Open the ERPNext project directory on your computer.

Step 2 — Open the project in the Docker container

Open the project using **VS Code / Dev Containers** so that the development environment runs inside the configured Docker container.

Step 3 — Navigate to the development folder

Inside the container, navigate to:

```
cd development
```

Step 4 — Navigate to **frappe-docker**

```
cd frappe-docker
```

Your path should now be roughly:

```
development/  
└── frappe-docker/
```

Step 5 — Start the Frappe/ERPNext development server

Run:

`bench start`

This starts the local development environment and makes the ERPNext/Frappe services available for development.

4. Making Changes to the Project

For development, the **recommended approach is to use Antigravity IDE** with the same project directory.

Instead of manually modifying files through different environments:

1. Open the existing project directory in **Antigravity IDE**.
2. Make your required code/configuration changes.
3. Test the changes locally.
4. Once everything is working, commit the changes.
5. Push them to GitHub.
6. Deploy the updated version to the server using the deployment procedure above.

Recommended Development Flow

Antigravity IDE

Make changes

Test locally

Commit changes

Push to GitHub

SSH into server

git pull

Docker Compose Down

Docker Compose Up --build

Updated application is running

5. Quick Command Reference

Pull latest code

git pull

Stop Docker application

sudo docker compose down

Rebuild and start Docker application

sudo docker compose up --build

Start ERPNext locally

cd development
cd frappe-docker
bench start

Super-Short Handover Version

Vyom Energy / ERP Deployment

1. Push updated code → GitHub
2. SSH → AWS Lightsail server
3. cd → project directory
4. git pull
5. sudo docker compose down
6. sudo docker compose up --build

ERPNext Local Startup

1. Open project directory
2. Open project in Docker Container
3. cd development
4. cd frappe-docker
5. bench start

Development

Use Antigravity IDE with the existing project directory → make changes → test → push to GitHub → deploy.
